## generated.
```

```r
match_info <- MatchBalance(balance_formula, data = estimation_nona, nboots = 1000, print.level = 0)

balance_test_before <- baltest.collect(match_info, var.names = covariates, after = FALSE) # balance bef
balance_test_before <- balance_test_before[, c("mean.Tr", "mean.Co", "T pval", "KS pval")]

balance_test_before |>
  kable(booktabs = T, digits = 3, align = rep('c', 4),
        col.names = c("Treatment Mean", "Control Mean", "T p-value", "KS p-value")) |>
  kable_styling(full_width = F, position = "center")
```

	Treatment Mean	Control Mean	T p-value	KS p-value
uribe_2002_proportion	0.431	0.467	0.005	0.004
uribe_2006_proportion	0.603	0.649	0.000	0.000
avg_schooling	5.261	5.072	0.002	0.015
literacy	84.635	87.495	0.000	0.000
log_pop	9.896	9.001	0.000	0.000
prop_rural	0.553	0.658	0.000	0.000
gdp_pcap_cons2005	5.805	6.388	0.057	0.370
mpi	68.743	67.150	0.120	0.002
gini	0.449	0.468	0.000	0.000
etv_state_pre	3.153	0.911	0.000	0.000

etv_nonstate_pre	80.892	29.604	0.000	0.000
dem_security	0.090	0.090	0.997	NA
hist_land_conflict	0.069	0.025	0.001	NA

These are almost all significantly different between treatment and control.

4.1.2 Matching covariates

Matching throws away non-matched control units

TODO: Why ATT? We are grabbing the control unit with the closest X_i What does closest mean? For Match(): normalized Euclidean distance

curse of dimensionality: the more covariates, the further Todo: should we think through each covariate and whether we really need it? Also: issue of overspecifying the model

Issue of discrepancy with multiple continuous variables Have to adjust for it (bias correction) through BiasAdjust = TRUE Subtracts off estimated discrepancy

TODO: Different combinations: replacement vs without (of controls to match to treated); how many matches; which algorithm (Coarse - too many covariates means too far distance; pre-processing - match then regression on only close); whether to drop treatment units (removes bias)

caliper: removes units with no common support

```
exact_matches <- ifelse(colnames(estimation_nona[,covariates]) %in% c("dem_security", "hist_land_confli

match_model_1 <- Match(Y = estimation_nona$trust_plebi_yes,
                       Tr = estimation_nona$treat_dicho,
                       X = estimation_nona[, covariates],
                       M = 1, # one-to-one matching
                       exact = exact_matches,
                       caliper = 2, #0.25 standard deviations dropped
                       Weight = 2, #inverse of variance
                       replace = TRUE,

4.2 Propensity score matching

4.2.1 Propensity score balance

```
# plot
ggplot(tibble(ps = estimation_nona$ps,
              treatment = as_factor(ifelse(estimation_nona$treat_dicho == 1, "Treated", "Control"))),
       aes(x = ps, col = treatment)) +
  geom_density() +
  labs(title = "Distribution of propensity scores", y = "Density", x = "Propensity Score") +
  xlim(c(0, 1)) +
  theme_minimal()
```

Very different; match by propensity to get balanced units.

4.2.2 Matching propensity scores

Compare units that have a comparable probability of getting treated.

```
match_ps <- Match(Y = estimation_nona$trust_plebi_yes,
                  Tr = estimation_nona$treat_dicho,
                  X = estimation_nona$ps,
                  M = 1,
                  estimand = "ATT")

match_data_ps <- estimation_nona[c(match_ps$index.treated,
                                   match_ps$index.control),] #723 treated, 723 control

## Disregarding ebalance convergence and re-running at optimal choice of numdims, 24
```

```
lm_weight_ker <- lm_robust(trust_plebi_yes ~ treat_dicho, weights = weight_model_kbal$w, data = estimati
lm_weight_ker_controls <- lm_robust(trust_plebi_yes ~ treat_dicho + uribe_2002_proportion + uribe_2006_p
```

```
# Examine bias bound due to remaining imbalances;
# gamma is 55
# https://cran.r-project.org/web/packages/KRLS/KRLS.pdf

plot(x = weight_model_kbal$dist_record[1,],
     y = sd(estimation_nona$trust_plebi_yes) * sqrt(55) * weight_model_kbal$dist_record[2,],
     ylab="biasbound",
     xlab="Num. dims of K balanced",
     pch=16)
```

above ones compare means; kernel compares means, and also x/2, and x squared, etc etc; each one of these is a dimension of K; kbal finds the dimensions of k that makes the treatment and control the most balanced (ebalance convergence); we want bias bound to be as low as possible. The plot shows the number of K and what bias bound it gives; in this case, 24 is the lowest: "Disregarding ebalance convergence and re-running at optimal choice of numdims, 24"

```
rm(balance_table_ps, match_ps, match_balance_ps, match_balance_ps_2, match_data_ps, match_data_ps_2, we
```

```

JEP: Adding controls makes it negative Propensity scores and kernel does not work well

cnmh: Adding controls makes it negative all matching and propensity score weighting looks good!

7. Sensitivity analysis

Hopefully using uribe 2002 as benchmark

```
#The previous estimate requires the assumption of no unobserved confounders for unbiasedness.
estimation_model <- lm(trust_plebi_yes ~ treat_dicho + uribe_2002_proportion + uribe_2006_proportion + a

estimation_sensitivity <- sensemakr(model = estimation_model,
                                    treatment = "treat_dicho",
                                    benchmark_covariates = "uribe_2002_proportion",
                                    kd = c(1, 5, 10, 15, 20), #1-3 times stronger than treatment
                                    ky = c(1, 5, 10, 15, 20), #1-3 times stronger than outcome
                                    q = 1, #reduction of 100% of current estimate - true effect of zero is p
                                    alpha = 0.05,
                                    reduce = T)
